PROG8245 – Machine Learning Frameworks

GitHub Repo - <https://github.com/DavisenV/PROG8245-Lab1.git>

Item	Explanation
"Correct answer"	A - The one-item sample contains `100`, so $\sigma = 0$. Every transaction except occurrences of `100` is returned.
"Why the other nine are wrong"	B - Repeated values are not the selection rule, deviation from the sample mean is used. C - The result is not always empty; values different from the sample mean are flagged. D - The function can return several transactions, not only the largest one. E - Middle-valued anomalies can also be returned, so only extremes are not guaranteed. F - Transactions equal to the sample mean are removed, so the list is modified. G - The function selects deviations greater than $1.5 \cdot \sigma$, not less than it. H - The code sets σ to zero for a one-element sample, avoiding `ValueError`. I - A list comprehension returns every qualifying transaction, not just the first one. J - The input values are integers, and the returned elements remain integers.
